

Meeting Notes and Reflections

Student Name: Havva Eva Canbulat

Student Number: 041068561

Course: Web Programming

Date: May 2026

Iteration 0 – Planning

The team met virtually to discuss the project requirements and how we would complete the assignment. We decided that each team member would independently create their own e-commerce store project using Node.js, Express.js, MongoDB Atlas, and Render deployment.

We agreed not to share code, but instead share ideas, troubleshooting suggestions, deployment updates, and API endpoints for integration testing.

We also discussed how automate.js would be used to test each team member's /getAll endpoint sequentially.

Reflection:

During the planning phase, I learned the importance of organizing work early and communicating clearly with team members. Planning helped reduce confusion later during deployment and testing.

Iteration 1 – Individual Implementation

I created my own e-commerce project called Eva Tech Store. I implemented CRUD operations and connected the application to MongoDB Atlas using Mongoose.

I added 5 products with the required fields:

- storeId
- storeName
- productId

- productName
- price

I deployed my project on Render and verified that the /getAll endpoint was working correctly.

Main deployment:

<https://evastoreproject.onrender.com>

GetAll endpoint:

<https://evastoreproject.onrender.com/getAll>

Reflection:

One challenge during this phase was configuring MongoDB Atlas and Render deployment correctly. I learned how environment variables and deployment settings work together in full-stack applications.

Iteration 2 – Integration and Testing

The team shared deployed /getAll endpoints for integration testing. I added the endpoints into automate.js and tested them sequentially.

Integrated endpoints:

Havva:

<https://evastoreproject.onrender.com/getAll>

Zineb:

<https://zinebstoreproject-1.onrender.com/getAll>

I used automate.js to test the endpoints and verify the output format. The tests displayed the email, test name, status code, and pass/fail result in the terminal.

Example output:

evaaksoy9@gmail.com - getAll to show all product - 200 - PASSED

ben0070@algonquinlive.com - getAll to show all product - 200 - PASSED

Reflection:

During integration testing, I learned how APIs from multiple deployed applications can be tested together. I also improved my debugging skills by fixing automate.js syntax and deployment issues.

Iteration 3 – Demoing

The team discussed the completed project modules, deployment progress, integration testing, and lessons learned throughout the assignment.

I prepared a demo video showing:

- frontend application
- MongoDB Atlas integration
- CRUD functionality
- Render deployment
- automate.js testing
- project structure in Visual Studio Code

Reflection:

This project improved my understanding of backend development, deployment, testing, and integration. I also learned the importance of teamwork, communication, and troubleshooting during software development projects.

Lessons Learned

Throughout this project, I learned how to build and deploy a full-stack Node.js and MongoDB application. I improved my understanding of Express.js routing, MongoDB Atlas integration, API testing, deployment, and frontend integration.

Areas I need to improve:

1. Deployment Troubleshooting

I experienced challenges with MongoDB Atlas IP access configuration and Render deployment settings. In the future, I would like to improve my troubleshooting speed and deployment knowledge.

2. Automated Testing

I learned how automate.js and sequential endpoint testing work, but I would like to improve my understanding of testing frameworks and automation scripting.

3. Time Management During Integration

Coordinating deployment links and integration testing with team members required careful timing and communication. I would like to improve project coordination and scheduling skills for future group projects.
